(54) **Industrial vehicle**

(57) A control apparatus for an industrial vehicle is disclosed. The vehicle has a rear axle that is swingable upon a straight travel of the vehicle and fixed upon a turning of the vehicle. A damper locks or unlocks the rear axle. A controller has a memory that stores a first value and a second value of an angular velocity rate that represents an angular velocity per a unit time. The controller activates or deactivates the damper. The controller activates the damper to lock the rear axle when the angular velocity rate is greater than the first value. The controller deactivates the damper to unlock the rear axle when the angular velocity rate is kept smaller than the second value for a predetermined time period after the angular velocity rate has become smaller than the second value.

## Description

The present invention relates to axle supporting apparatus for industrial vehicles, and more particularly, to an apparatus for locking swingable axles of industrial vehicles.

A typical forklift truck has a rear axle that is supported by a body frame. The rear axle is swung with respect to the body frame by lateral acceleration, or centrifugal force, that is produced when the traveling forklift truck changes directions. This degrades the traveling stability of the forklift truck. Thus, the traveling speed of the forklift truck must be decreased when changing directions.

Japanese Unexamined Patent Publication No. 58-211903 describes a forklift truck that locks the swinging of an axle when the truck turns. The forklift truck has a detecting means that detects centrifugal force when the truck is turned. When the centrifugal force becomes greater than a predetermined level, the swinging of the axle with respect to the body frame is restricted. In other words, the axle is locked. This enables stable turning of the forklift truck without having to slow down the vehicle. However, when the forklift truck successively changes direction within a short period of time, for example, when the vehicle turns right and then turns left immediately afterward, the centrifugal force, for an instant, is less than the predetermined level. This releases the locking of the axle regardless of the vehicle changing directions. As a result, the forklift truck becomes unstable when successively turned in different directions.

Japanese Unexamined Patent Publication No. 58-214406 describes a forklift truck that locks its axle when the rotated angle of a steering wheel and the speed of the vehicle become greater than predetermined values. However, when the vehicle is successively turned in different directions, for an instant, the rotated angle of the steering wheel becomes smaller than the predetermined angle. Thus, in the same manner as the forklift truck of Publication No. 58-211903, this releases the locking of the axle and causes instability.

Among the four wheels (two front wheels and two rear wheels) of a forklift truck, one of the wheels may be lifted from the ground depending on the weight of the object held by the forks when the axles are locked during turning. For example, when a heavy object is held on the forks, the center of gravity of the vehicle is displaced toward the front of the forklift truck. This may lift one of the rear wheels from the ground if one of the axles are locked. If the axles are locked when a relatively light object is held on the forks, the balance weight provided at the rear of the vehicle may cause one or the front wheels to raise from the ground.

Typically, torque is transmitted to the front wheels to drive forklift trucks. The steering angle is transmitted to the rear wheels to steer the vehicle. Accordingly, if the rear axle is locked when a relatively light object is held on the forks, one of the front wheels, which function as the drive wheels, may be lifted away from the ground.

This decreases traction between the front wheels and the ground. As a result, the driving force of the vehicle becomes insufficient. This hinders smooth operation of the forklift truck.

If a heavy object is held on the forks, the center of gravity, which is near the front of the vehicle, increases the traction force of the front wheels. Accordingly, the locking of the axle does not affect the driving force of the vehicle. However, when the center of gravity is near the front of the vehicle, the vehicle tends to swing in a forward direction. As a result, the forklift truck becomes unstable when lifting and lowering objects and when traveling with the heavy object held on the forks. This tendency is stronger if the object is held at a high position, which raises the center of gravity.

Accordingly, it is an objective of the present invention to provide an industrial vehicle that is capable of traveling in a stable manner.

A further objective of the present invention is to provide an industrial vehicle that is capable of lifting and lowering objects in a stable manner.

For achieving the above objectives, an improved control apparatus for an industrial vehicle is provided. The vehicle includes a rear axle, said rear axle being swingable upon a straight travel of the vehicle and fixed upon a turning of the vehicle. The apparatus comprises holding means for selectively locking and unlocking the rear axle, memory means for storing a first value and a second value of an angular velocity rate, wherein said angular velocity rate represents an angular velocity per a unit time, wherein said first value is predetermined to indicate turning of the vehicle when the angular velocity rate is greater than the first value, and wherein said second value is predetermined to indicate the straight travel of the vehicle when the angular velocity rate is smaller than the second value and control means for selectively activating and deactivating the holding means, said control means activates the holding means to lock the rear axle when the angular velocity rate is greater than the first value, said control means deactivates the holding means to unlock the rear axle when the angular velocity rate is kept smaller than the second value for a predetermined time period after the angular velocity rate has become smaller than the second value.

The features of the present invention that are believed to be novel are set forth with particularity in the appended claims. The invention, together with objects and advantages thereof, may best be understood by reference to the following description of the presently preferred embodiments together with the accompanying drawings in which:

An industrial vehicle, or forklift truck 1 having a body frame 1a is shown in Fig. 1. A pair of left and right outer masts 2 are mounted on the front of the forklift truck 1. A pair of inner masts 3 are provided between the outer masts 2. A fork 4 is mounted on each inner mast 2. The fork 4 is lifted and lowered with respect to the associated inner mast 2. A tilting cylinder 5 having a body 5a and a cylinder rod 5b is provided for each outer mast 2. The body 5a is coupled to the body frame 1a while the cylinder rod 5b is coupled to the associated outer mast 2. The outer masts 2 and the forks 4 are tilted by the tilting cylinders 5. A lifting cylinder 6 having a body 6a and a rod 6b is provided for each inner mast 2. The body 6a is coupled to the body frame 1a while the cylinder rod 6b is coupled to the associated inner mast 2. The inner masts 3 are lifted and lowered by the lifting cylinders 6, on which the forks 4 are mounted.

A pair of front wheels 7 are mounted at the front portion of the frame 1a. As shown in Fig. 4, the front wheels 7 are connected to an engine E by means of a differential gear U and a transmission D. Hence, each front wheel 7 is driven by the engine E.

A pair of rear wheels 8 are mounted at the rear portion of the frame 1. A structure for connecting the rear wheels 8 is shown in Fig. 2. A rear axle 11 is provided at the lower rear portion of the frame 1a extending between the left and right sides of the frame 1a. The rear axle 11 is pivotal about a center pin 11a. The rear wheels 8 are mounted on the ends of the rear axle 11. The direction of the rear wheels 8 is changed by turning a steering wheel 10, which is installed in a driver's compartment 9.

A damper, or shock absorber 12 is connected between the body frame 1a and the rear axle 11. The shock absorber 12 is a double action hydraulic cylinder and absorbs the force that is applied to the rear wheels 8. The shock absorber 12 includes a cylindrical body 12a, a piston 12b accommodated in the body 12a, and a piston rod 12c connected to the piston 12b. The distal end of the piston rod 12c is connected to the rear axle 11.

A first compartment R1 and a second compartment R2 are defined in the shock absorber 12 by the piston 12b. A first oil passage P1 is connected to the first

chamber R1 while a second oil passage P2 is connected to the second chamber R2. The first and second oil passages P1, P2 are connected to an electromagnetic switching valve 13. The switching valve 13 includes a body and a spool. The spool has a connecting portion 14 and a disconnecting portion 15. A third oil passage P3 and a fourth oil passage P4 are connected to the switching valve 13. The third oil passage P3 is connected with the fourth oil passage P4. The fourth oil passage P4 is connected to an accumulator 16 in which hydraulic oil is reserved. A throttle valve 17 is provided in the second oil passage P2.

In the stitching valve 13, the spool moves with respect to the body and selectively connects the connecting portion 14 and the disconnecting portion 15 with the oil passages P1 to P4. When the connecting portion 14 is connected to the oil passages P1 to P4, the first oil passage P1 is communicated with the third oil passage P3 and the second oil passage P2 is communicated with the fourth oil passage P4. In this state, the first and second chambers R1, R2 are communicated with the accumulator 16. This permits hydraulic oil to flow in and out of the first and second chambers R1, R2. Thus, the shock absorber 12 enables pivoting of the rear axle 11. When the disconnecting portion 15 is connected with the oil passages P1 to P4, the oil passages P1 to P4 are disconnected from one another. In this state, the piston 12b of the shock absorber 12 is locked. Thus, the shock absorber 12 prohibits pivoting of the rear axle 11.

As shown in Fig. 1, a balance weight 19 is mounted on the rear of the forklift truck 1. A piezo-electric sensor, or gyroscope 20, is arranged on the balance weight 19. The gyroscope 20 detects the angular velocity, or yaw rate  $\omega$  of the forklift truck 1 when changing directions. As shown in Figs. 1 and 3, an acceleration sensor 21 is arranged on an instrument panel W provided in the driver's compartment 9. The acceleration sensor 21 is located midway between the front wheels 7. Actual lateral acceleration, or actual centrifugal force  $F_a$ , that is produced when the forklift truck 1 changes directions is detected by the acceleration sensor 21.

As shown in Figs. 1 and 5, a limit switch 24 is arranged at the upper portion of the outer mast 2 to detect the vertical position of the associated fork 4. The limit switch 24 is located at a position that is lower than the top end of the outer mast 2 by one fourth the length of the mast 2. A pressure sensor 25 is provided at the bottom end of the lifting cylinder 6 to detect the hydraulic pressure of the hydraulic oil that acts on the lifting cylinder 6.

As shown in Fig. 2, a steering angle sensor 22 is arranged on one of the rear wheels 8 to detect the steering angle  $\theta$  of the rear wheels 8. As shown in Fig. 4, a vehicle speed sensor 23 is provided in the forklift truck 1 to detect the rotating speed of the differential gear U, or the traveling speed  $v$  of the forklift truck 1.

The electrical structure of a controller 31 employed in the above industrial vehicle will now be described with reference to an electric block diagram illustrated in Fig.

7.

The controller 31 has a memory 31a and a timer 31b that are included in a central processing unit (CPU), a read only memory (ROM), and other parts. The controller 31 also has an input terminal and an output terminal. The gyroscope 20, the acceleration sensor 21, the steering angle sensor 22, the vehicle speed sensor 23, the limit switch 24, and the pressure sensor 25 are connected to the input terminal. The electromagnetic switching valve 13 is connected to the output terminal of the controller 31.

When the forklift truck 1 changes direction, the gyroscope 20 sends an angular velocity signal, which corresponds to the detected yaw rate  $\omega$ , to the controller 31. When the forklift truck 1 changes direction, the acceleration sensor 21 sends an actual centrifugal force signal, which corresponds to the detected actual centrifugal force  $F_a$ , to the controller 31. The steering angle sensor 22 sends a steering angle signal, which corresponds to the detected steering angle  $\theta$  of the rear wheels 8, to the controller 31. The vehicle speed sensor 23 sends a speed signal, which corresponds to the detected speed  $v$  of the forklift truck 1, to the controller 31.

The limit switch 24 sends an activated signal to the controller 31 when actuated as the associated fork 4 is lifted above a reference height  $Z_{ref}$ . The reference height  $Z_{ref}$  is located at a position that is lower than the top end of the outer mast 2 by approximately one fourth the length of the outer mast 2. The pressure sensor 25 sends a hydraulic pressure signal, which corresponds to the detected hydraulic pressure  $y$  applied to the lifting cylinder 6, to the controller 31.

Based on the angular velocity signal sent from the gyroscope 20, the controller 31 computes the angular velocity altering rate, or the yaw rate altering rate  $\Delta\omega/\Delta T$ . The altering rate  $\Delta\omega/\Delta T$  corresponds to the angular acceleration. The controller 31 obtains the altering rate  $\Delta\omega/\Delta T$  by differentiating the yaw rate  $\omega$  with respect to time.

The controller 31 determines lateral acceleration based on centrifugal force. The controller 31 computes centrifugal force based on the traveling speed signal from the vehicle speed sensor 23 and the angular velocity signal from the gyroscope 20. The computed centrifugal force  $F_b$  differs from the actual centrifugal force detected by the acceleration sensor 21. Thus, there is a slight difference between the values of the actual centrifugal force  $F_a$  and the computed centrifugal force  $F_b$ . The computed centrifugal force  $F_b$  is obtained by multiplying the traveling speed  $v$  with the angular velocity  $\omega$ , as represented by the following equation (1):

$$F_b = v \times \omega \quad (1)$$

Reference values of the yaw rate altering rate  $\Delta\omega/\Delta T$  are stored in the memory 31a of the controller 31. The reference rate values include a maximum reference value  $K_{max}$ , which is referred to when the rate

$\Delta\omega/\Delta T$  increases, and a minimum reference value  $K_{min}$ , which is referred to when the rate  $\Delta\omega/\Delta T$  decreases. The controller 31 starts the output of a locking signal when the value of the computed altering rate  $\Delta\omega/\Delta T$  changes from a value equal to or smaller than the maximum reference value  $K_{max}$  to a value greater than the maximum reference value  $K_{max}$ . When the locking signal is being output, the controller 31 compares the altering rate  $\Delta\omega/\Delta T$  with the minimum reference value  $K_{min}$ . If the value of the altering rate  $\Delta\omega/\Delta T$  changes from a value equal to or greater than the minimum reference value  $K_{min}$  to a value smaller than the minimum reference value  $K_{min}$ , the controller 31 stops the output of the locking signal.

The controller 31 waits for a predetermined time length  $T$  to elapse before stopping the output of the locking signal. More specifically, a timer 31b starts measuring time when the value of the altering rate  $\Delta\omega/\Delta T$  changes from a value equal to or greater than the minimum reference value  $K_{min}$  to a value smaller than the minimum reference value  $K_{min}$ . When the measured time reaches the time length  $T$ , the controller 31 stops the output of the locking signal. The timer 31b is controlled by the controller 31 so as to stop measuring time when the value of the altering rate  $\Delta\omega/\Delta T$  becomes equal to or greater than the minimum reference value  $K_{min}$ .

Reference values of the centrifugal force acting on the forklift truck 1 are stored in the memory 31a of the controller 31. The reference values include a centrifugal force maximum reference value  $H_{max}$ , which is referred to when the centrifugal force increases, and a centrifugal force minimum reference value  $H_{min}$ , which is referred to when the centrifugal force decreases. The controller 31 starts outputting a locking signal when the absolute value of the computed centrifugal force  $F_b$  changes from a value equal to or smaller than the maximum reference value  $H_{max}$  to a value greater than the maximum reference value  $H_{max}$ . During the output of the locking signal, the controller 31 stops the locking signal if the absolute value of the computed centrifugal force  $F_b$  becomes smaller than the minimum reference value  $H_{min}$ .

The controller 31 determines the weight of the load on the forks 4 based on the signal from the pressure sensor 25. The controller 31 further computes and locates the center of gravity  $G$  (Fig. 6) of the forklift truck 1 based on the weight of the load. The center of gravity  $G$  corresponds to the center of gravity of the combined mass of the vehicle and the load. In this case, the controller computes the center of gravity  $G$  under the assumption that the inclination of the outer masts 1 is maximum as shown in the dotted lines of Fig. 5. A reference pressure value  $N_{ref}$  of the hydraulic pressure  $y$  applied to the lifting cylinder 6 is stored in the memory 31a of the controller 31.

The controller 31 computes the hydraulic pressure  $y$  applied to the lifting cylinder 6 based on the detecting signal from the pressure sensor 25 when receiving an

activated signal from the limit switch 24. If the hydraulic pressure  $y$  is equal to or greater than the reference pressure value  $N_{ref}$ , the controller 31 sends a locking signal to the electromagnetic switching valve 13.

More specifically, the controller 31 sends a locking signal to the switching valve 13 when any one of the following six conditions is satisfied:

(a) The yaw rate altering rate  $\Delta\omega/\Delta T$  is greater than the maximum reference value  $K_{max}$ .

(b) The yaw rate altering rate  $\Delta\omega/\Delta T$  becomes less than the maximum reference value  $K_{max}$  from a value greater than the maximum reference value  $K_{max}$  but is greater than the minimum reference value  $K_{min}$ .

(c) The yaw rate altering rate  $\Delta\omega/\Delta T$  is less than the minimum reference value  $K_{min}$  within the predetermined time length  $T$ , which is measured from when the altering rate  $\Delta\omega/\Delta T$  falls below the minimum reference value  $K_{min}$  from the state where condition (b) is satisfied.

(d) The absolute value of the computed centrifugal force  $F_b$  is greater than the maximum reference value  $H_{max}$ .

(e) The absolute value of the computed centrifugal force  $F_b$  becomes equal to or less than the maximum reference value  $H_{max}$  from a value greater than the maximum reference value  $H_{max}$  but is greater than the minimum reference value  $H_{min}$ .

(f) The activated signal is sent from the limit switch 24 and the hydraulic pressure  $y$  applied to the lifting cylinder 6 is equal to or greater than the reference pressure value  $N$ .

The electromagnetic switching valve 13 has a solenoid that is excited by the locking signal. This causes the disconnecting portion 15 of the switching valve 13 to be selectively connected with the oil passages  $P_1$  to  $P_4$ . As a result, the switching valve 13 closes the first and second oil passages  $P_1$ ,  $P_2$  and locks the rear axle 11 with the shock absorber 12. When not receiving the locking signal, the solenoid is de-excited. This causes the connecting portion 14 to be selectively connected to the oil passages  $P_1$  to  $P_4$ . As a result, the switching valve 13 permits hydraulic oil to flow in and out of the first and second chambers  $R_1$ ,  $R_2$ . In such state, the body frame 1a is swingable with respect to the rear axle 11.

The controller 31 locks the rear axle 11 with the switching valve 13 in accordance with the flowchart illustrated in Figs. 8(A) and 8(B). It is presumed here that the locking signal is not being output from the controller 31 and that the rear axle 11 is swingable when the controller 31 enters the control processing of Fig. 8(A).

In the flowcharts, the character "S" stands for "step." At step 101, the controller 31 reads the traveling speed  $v$  of the forklift truck 1 based on the traveling speed signal sent from the vehicle speed sensor 23. At step 102, the controller 31 reads the yaw rate  $\omega$  based on the angular velocity signal sent from the gyroscope 20. At step 103, the controller 31 obtains the computed centrifugal force  $F_b$  by applying the traveling speed  $v$  and the yaw rate  $\omega$  to the equation (1).

At step 104, the controller 31 computes the yaw rate altering rate  $\Delta\omega/\Delta T$  based on the yaw rate  $\omega$ . The controller 31 has a low pass filter function, which is used in step 105 to eliminate high frequency noise from the altering rate  $\Delta\omega/\Delta T$ .

At step 106, the controller 31 determines whether the absolute value of the computed centrifugal force  $F_b$  ( $|F_b|$ ) is greater than the maximum reference value  $H_{max}$ . If it is determined that the altering rate  $\Delta\omega/\Delta T$  is greater than the maximum reference value  $H_{max}$ , the controller 31 proceeds to step 107 and continuously outputs a locking signal to the electromagnetic switching valve 13 and maintains the solenoid thereof in an excited state. This employs the disconnecting portion 15 of the switching valve 13 and causes the shock absorber 12 to hold the rear axle 11 in a locked state. Thus, the rear axle 11 is held in a manner such that swinging is restricted. The controller 31 then returns to step 101 and repeats the execution of the above steps.

When it is determined that the absolute value  $|F_b|$  is equal to or smaller than the maximum reference value  $H_{max}$ , the controller 31 proceeds to step 108. At step 108, the controller 31 determines whether the absolute value  $|F_b|$  is smaller than the minimum reference value  $H_{min}$ . If, in step 108, it is determined that the absolute value  $|F_b|$  is smaller than the minimum reference value  $H_{min}$ , the controller 31 proceeds to step 109 and stops the output of the locking signal. The controller 31 then proceeds to step 110. If, in step 108, it is determined that the absolute value  $|F_b|$  is equal to or greater than the minimum reference value  $H_{min}$ , the controller 31 proceeds to step 110 without outputting the locking signal.

At step 110, the controller 31 determines whether the yaw rate altering rate  $\Delta\omega/\Delta T$  is greater than the maximum reference value  $K_{max}$ . When it is determined that the altering rate  $\Delta\omega/\Delta T$  is greater than the maximum reference value  $K_{max}$ , the controller 31 proceeds to step 111 and outputs the locking signal to the switching valve 13. This fixes the shock absorber 12 and holds the rear axle 11 in a locked state. The controller 31 then returns to step 101 and repeats the execution of the above steps. If it is determined that the altering rate  $\Delta\omega/\Delta T$  is equal to or less than the maximum reference value  $K_{max}$  in step 110, the controller 31 proceeds to step 112.

At step 112, the controller determines whether the altering rate  $\Delta\omega/\Delta T$  is smaller than the minimum reference value  $K_{min}$ . When it is determined that the altering rate  $\Delta\omega/\Delta T$  is smaller than the minimum reference value

$K_{min}$ , the controller 31 proceeds to step 113 and determines whether the time measured by the timer 31b has reached the predetermined time length  $T$ . When it is determined that the time length  $T$  has not yet elapsed, the controller 31 returns to step 101 and repeats the above steps. If it is determined that the time length  $T$  has elapsed, the controller 31 proceeds to step 114 and stops the output of the locking signal. Afterwards, the controller 31 returns to step 101.

The controller 31 then proceeds to step 112 and determines whether the value of the hydraulic pressure  $y$ , which is obtained based on the signal from the pressure sensor 25, is equal to or greater than the reference pressure value  $N_{ref}$ . When it is determined that the hydraulic pressure  $y$  is equal to or greater than the reference value  $N_{ref}$ , the controller 31 proceeds to step 116 and determines whether the activated signal is being output from the limit switch 24. If it is determined that the activated signal is being output from the limit switch 24, the controller 31 proceeds to step 118 and continues to output the locking signal.

If it is determined that the value of the hydraulic pressure  $y$  is smaller than the reference value  $N_{ref}$  in step 115, the controller 31 proceeds to step 117 and stops outputting the locking signal. The controller 31 also proceeds to step 117 and stops outputting the locking signal if it is determined that the activated signal is not being output from the limit switch 24 in step 116.

The processing performed by the controller 31 when the forklift truck 1 is turned to the right from a state in which it is traveling straight will now be described with reference to Fig. 11. When the forklift truck 1 turns right, the value of the steering angle  $\theta$  becomes positive and when turning left, the value of the steering angle  $\theta$  becomes negative. In the same manner, the values of the yaw rate  $\omega$ , the actual centrifugal force  $F_a$ , and the computed centrifugal force  $F_b$  become negative when the forklift truck 1 turns left, and positive when the truck 1 turns right.

When the operator of the forklift truck 1 steers the steering wheel 10 and turns the forklift truck 10 to the right, the value of the steering angle  $\theta$  increases. As the value of the steering angle  $\theta$  increases, the values of the yaw rate  $\omega$ , the computed centrifugal force  $F_b$ , the actual centrifugal force  $F_a$ , and the yaw rate altering rate  $\Delta\omega/\Delta T$  are each increased accordingly. The altering rate  $\Delta\omega/\Delta T$  is the first to increase among these values and becomes greater than the maximum reference value  $K_{max}$ . The controller 31 locks the rear axle 11 when the altering rate  $\Delta\omega/\Delta T$  becomes greater than the maximum reference value  $K_{max}$ . At this point, the value of the computed centrifugal force  $F_b$  is smaller than the maximum reference value  $H_{max}$ . Accordingly, when the turning of the forklift truck 1 begins, the rear axle 11 is locked by the altering rate  $\Delta\omega/\Delta T$  before being locked by the computed centrifugal force  $F_b$ .

As the value of the steering angle  $\theta$  further increases, the values of the yaw rate  $\omega$ , the computed centrifugal force  $F_b$ , and the actual centrifugal force  $F_a$

are each increased accordingly. This causes the absolute value of the computed centrifugal force  $|F_b|$  to become greater than the maximum reference value  $H_{max}$ . At this point, the altering rate  $\Delta\omega/\Delta T$  is greater than the maximum reference value  $K_{max}$  and the rear axle 11 is held in a locked state.

When the operator continues to turn the forklift truck 1 by holding the steering wheel 10 at the same predetermined angle, resulting in continuation of the same steering angle  $\theta$ , the yaw rate  $\omega$ , the computed centrifugal force  $F_b$ , and the actual centrifugal force  $F_a$  are maintained at constant values. When the value of the steering angle  $\theta$  becomes constant, the value of the altering rate  $\Delta\omega/\Delta T$  starts decreasing and becomes smaller than the minimum reference value  $K_{min}$ . At this point, the computed centrifugal force  $F_b$  is greater than the maximum reference value  $H_{max}$ . Thus, the controller 31 outputs the locking signal since the computed centrifugal force  $F_b$  is greater than the maximum reference value  $H_{max}$ . Accordingly, the rear axle 11 remains in a locked state.

The above processing is executed in the same manner when the forklift truck 1 is steered to the left from a state in which it is traveling straight. Thus, when the forklift truck 1 is driven in a straight direction and then steered either to the right or to the left, the altering rate  $\Delta\omega/\Delta T$  first becomes greater than the maximum reference value  $K_{max}$  and locks the rear axle 11. The altering rate  $\Delta\omega/\Delta T$  then becomes smaller than the minimum reference value  $K_{min}$ . However, since the absolute value of the centrifugal force  $|F_b|$  is greater than the maximum reference value  $H_{max}$ , the rear axle 11 remains in a locked state.

The processing performed by the controller 31 when the forklift truck 1 is steered to the right and then successively steered to the left will now be described with reference to Fig. 12. When the forklift truck 1 is steered to the right in a manner such that the value of the steering angle  $\theta$  is constant and is then steered to the left by turning the steering wheel 10 so as to decrease the value of the steering angle  $\theta$ , the yaw rate  $\omega$  and the computed centrifugal force  $F_b$  start to decrease from the predetermined values. When the computed centrifugal force  $F_b$  corresponds to the predetermined value, the centrifugal force  $F_b$  exceeds the maximum reference value  $H_{max}$ . Thus, the controller 31 outputs the locking signal and locks the rear axle 11. The value of the altering rate  $\Delta\omega/\Delta T$  starts to increase as the steering angle  $\theta$  decreases and becomes greater than the maximum reference value  $K_{max}$ . At this point, the computed centrifugal force  $F_b$  is greater than the minimum reference value  $H_{min}$ .

A further decrease of the steering angle  $\theta$  causes the computed centrifugal force  $F_b$  to become smaller than the minimum reference value  $K_{min}$ . However, the controller 31 continues to output the locking signal since the altering rate  $\Delta\omega/\Delta T$  is greater than the maximum reference value  $K_{max}$ .

The altering rate  $\Delta\omega/\Delta T$  is maximum when the

steering angle  $\theta$  becomes close to zero degrees. The forklift truck 1 begins to turn left as the value of the steering angle  $\theta$  reaches zero degrees and then further decreases. The decrease in the value of the steering angle  $\theta$  causes further decrease of the values of the yaw rate  $\omega$  and the computed centrifugal force  $F_b$ . The values of the yaw rate  $\omega$  and the computed centrifugal force  $F_b$  become negative and continue to further decrease. This increases the absolute values of the yaw rate  $\omega$  and the computed centrifugal force  $F_b$  ( $|F_b|$ ,  $|\omega|$ ). Thus, the absolute value of the computed centrifugal force  $|F_b|$  becomes greater than the maximum reference value  $H_{max}$ . At this point, the altering rate  $\Delta\omega/\Delta T$  is equal to or greater than the minimum reference value  $K_{min}$ . Since the conditions of  $|F_b| > H_{max}$  and  $\Delta\omega/\Delta T > K_{min}$  are satisfied, the controller 31 continues to output the locking signal. Thus, the rear axle 11 remains locked.

A further decrease of the steering angle  $\theta$  causes the altering rate  $\Delta\omega/\Delta T$  to become smaller than the minimum reference value  $K_{min}$ . However, the controller 31 continues to output the locking signal and keeps the rear axle 11 in a locked state. The locking signal is continued prior to the expiration of the predetermined time length  $T$ , which is measured from when the altering rate  $\Delta\omega/\Delta T$  became smaller than the minimum reference value  $K_{min}$ . Also, the locking signal is continued as long as the absolute value of the computed centrifugal force  $|F_b|$  is greater than the maximum reference value  $H_{max}$ . When the operator stops turning the steering wheel 10 and holds the steering angle  $\theta$  at a predetermined angle, the values of the yaw rate  $\omega$  and the computed centrifugal force  $F_b$  become constant. Furthermore, the value of the altering rate  $\Delta\omega/\Delta T$  becomes zero.

When the predetermined time length  $T$  elapses, the conditions related to the altering rate  $\Delta\omega/\Delta T$  for outputting the locking signal fail to be met. However, the conditions related to the computed centrifugal force  $F_b$  remain satisfied. Accordingly, the controller 31 continues to output the locking signal and keeps the rear axle 11 in a locked state.

When the forklift truck 1 turns right and then left successively, there is a period  $Y_1$  during which the conditions for outputting the locking signal related to the computed centrifugal force  $F_b$  are unsatisfied when the steering angle  $\theta$  is in the vicinity of zero degrees. However, the conditions for outputting the centrifugal force  $F_b$  related to the altering rate  $\Delta\omega/\Delta T$  are satisfied. Thus, the rear axle 11 is constantly in a locked state when the forklift truck 1 turns right and then left successively. Holding the steering angle  $\theta$  at a predetermined angle to steer the forklift truck 1 further to the left ends a period  $Y_2$ , at which the conditions for outputting the locking signal related to the altering rate  $\Delta\omega/\Delta T$  are satisfied. However, since the conditions for outputting the locking signal related to the computed centrifugal force  $F_b$  are satisfied, the rear axle 11 remains in a locked state. Accordingly, when the forklift truck 1 turns right

and then left successively, the rear axle 11 remains in a locked state.

The above processing is carried out in the same manner when the forklift truck 1 turns left and then right successively.

Fig. 12 shows the roll angle of the forklift truck 1 when in a rolling state. The roll angle is detected by a rolling sensor (not shown) provided on the body frame 1a.

As described above, in addition to the locking signal based on the altering rate  $\Delta\omega/\Delta T$ , the controller 31 outputs a locking signal based on the computed centrifugal force  $F_b$ . Accordingly, during successive turning of the forklift truck 1, the locking signal based on the altering rate  $\Delta\omega/\Delta T$  is output even when the locking signal based on the computed centrifugal force  $F_b$  is not output when the steering angle  $\theta$  is close to zero degrees. Thus, when the forklift truck 1 turns right and then left successively, the rear axle 11 is constantly maintained in a locked state. This enables the forklift truck 1 to change directions in a stable manner.

The control performed by the controller 31 when the forklift truck 1 transports loads will now be described.

Fig. 6 is an explanatory diagram that shows how a center of gravity  $G$  of the forklift truck 1 changes in accordance with the weight of the load carried on the forks 4 of the forklift truck 1. Diagonal lines have been drawn between the left front wheel 7 and the right rear wheel 8 and between the right front wheel 7 and the left rear wheel 8. The center of gravity, when there is no load carried on the forks 4, is denoted as  $G_1$  and is located rearward with respect to the intersecting point  $X$  of the two diagonal lines. The weight of a load carried by the forks 4 causes the center of gravity  $G$  to move forward between the center of gravity  $G_1$  and the intersecting point  $X$ . Thus, the traction force of the rear wheels 8 increases, and the traction force of the front wheels 7 decreases. In such state, one of the front wheels 7 may be lifted from the ground. Accordingly, the controller 31 does not output the locking signal. This allows swinging of the rear axle 11. In this case, swinging of the rear axle 11 decreases the traction force of the rear wheels 8 and increases the traction force of the front wheels 7. The value of the hydraulic pressure  $y$  applied to the lifting cylinder 6 when the load on the forks 4 coincides the center of gravity  $G$  with the intersecting point  $X$  is set as the reference pressure value  $N_{ref}$ .

The center of gravity of the forklift truck 1, when the weight of the load carried by the forks 4 becomes equal to the maximum payload of the forklift truck 1, is denoted as  $G_2$  and is located in front of the intersecting point  $X$ . When the center of gravity  $G$  of the forklift truck 1 is located between the center of gravity  $G_2$  and the intersecting point  $X$ , the traction force of the front wheels 7 increases. In such state, one of the rear wheels 8 may be lifted away from the ground. However, since the traction force of the front wheels 7, which are the drive wheels, is satisfactory, the rear axle 11 may be locked without interfering with the travel of the forklift

truck 1.

However, lifting the forks 4 to a position above the reference height  $Z_{ref}$  moves the center of gravity  $G$  upward. This causes the forklift truck 1 to become unstable laterally. At this point, the controller 31 outputs the locking signal to lock the rear axle 11 to enhance the stability of the forklift truck 1.

A second embodiment of the present invention will now be described. In this embodiment, the forklift truck 1 is not equipped with the gyroscope and the acceleration sensor. An assumed yaw rate  $\omega_x$  is obtained based on the steering angle  $\theta$  and the traveling speed  $v$ . The objective of this embodiment is to provide a structure that is capable of obtaining the same advantages of the first embodiment while having a decreased number of parts and a more cost-efficient structure.

With reference to the flowchart illustrated in Fig. 13, the controller 31 reads the traveling speed  $v$  at step 201 and the steering angle  $\theta$  at step 202. At step 203, the controller 31 obtains the inverse of a turning radius  $r$  that is computed based on the steering angle  $\theta$ .

At step 204, the controller 31 computes an assumed centrifugal force  $F_x$ . The assumed centrifugal force  $F_x$  corresponds to the computed centrifugal force  $F_b$  of the first embodiment. However, since the forklift truck 1 does not have a gyroscope, the yaw rate is not detected. Instead, an assumed yaw rate value  $\omega_x$  is obtained by dividing the traveling speed  $v$  with the turning radius  $r$  ( $\omega_x = v/r$ ). Thus, the assumed centrifugal force  $F_b$  is computed using the equation of  $F_x = 2v/r$ , whereas, in the first embodiment, the computed centrifugal force is computed using the equation of  $F_b = vx\omega$ . At step 205, the controller 31 obtains the assumed yaw rate altering rate  $\Delta\omega_x/\Delta T$ . The purpose of executing these steps are the same as the first embodiment and will not be described for the sake of brevity.

The absolute value of the assumed centrifugal force  $F_x$  is compared with the maximum reference value  $H_{max}$  in step 206 and the minimum reference value  $H_{min}$  in step 208. The comparison is carried out with reference to a map illustrated in Fig. 10. The altering rate  $\Delta\omega_x/\Delta T$  is compared with the maximum reference value  $K_{max}$  in step 210 and the minimum reference value  $K_{min}$  in step 212. The purpose of executing these steps is the same as that of the first embodiment. After execution of steps 207, 211, 213, and 214, the controller 31 proceeds to step 115.

A third embodiment of the present invention will now be described with reference to Figs. 14 to 16. In this embodiment, the rear axle 11 is gradually released from the locked state by a hydraulic unit that operates the shock absorber 12 in a gradual manner. When the rear axle 11 is locked, the interior of the shock absorber 12 is highly pressurized. If the pressure in the shock absorber 12 is suddenly decreased, the rear axle 11 may start to swing in a sudden manner. The operating mechanism of the shock absorber 12 employed in this embodiment regulates such undesirable swinging of the rear axle 11.

In this embodiment, an electromagnetic proportional valve 130 is employed in lieu of the electromagnetic switching valve 13. The controller 31 sends a duty signal to the proportional valve 130 by way of a driving circuit (not shown) to adjust the opening area of the proportional valve 130. The structure of the valve 130 will now be described.

As shown in Fig. 14, the proportional valve 130 includes a cylindrical body 14 and a spool 15, which is slidably accommodated in the body 14. The spool 15 is driven by an electromagnetic solenoid 13a and a spring 13b. The spool 15 is constantly urged toward an opening position by the spring 13b. When a duty signal from the controller 31 excites the solenoid 13a, the spool 15 is moved to a closing position. The first, second, third, and fourth oil passages P1, P2, P3, P4, are respectively connected with first, second, third, and fourth holes E1, E2, E3, E4, which extend through the wall of the body 14. The spool 15 is provided with a first groove F1 and a second groove F2. When the spool 15 is at the opening position, the first groove F1 is aligned with the first and third holes E1, E3, and the second groove F2 is aligned with the second and fourth holes E2, E4. Thus, the first groove F1 connects the first oil passage P1 to the third oil passage P3, and the second groove F2 connects the second oil passage P2 to the fourth oil passage P4.

The spool 15 is moved for a distance corresponding to the duty ratio of the duty signal sent from the controller 31. The movement of the spool 15 alters the aligned area between the first groove F1 and the corresponding holes E1, E3, and between the second groove F2 and the corresponding holes E2, E4. In other words, the movement of the spool 15 alters the opening area of the proportional valve 130. This adjusts the flow rate of the hydraulic oil flowing through the oil passages P1-P4.

Hydraulic oil is supplied to the oil passages P1-P4 from the accumulator 16. The accumulator 16 also supplies oil to the lifting cylinder 6.

The controller 31 locks the shock absorber 12 by means of the proportional valve 130 when any one of the conditions (a) to (f) for outputting the locking signal (described in the first embodiment) is satisfied. This, in turn, locks the rear axle 11. The controller 31 outputs the duty signal to the proportional valve 130 when none of the signal outputting conditions (a) to (f) is met. When first output, the duty ratio of the duty signal is one hundred percent. The duty ratio decreases gradually until it reaches zero percent. Thus, as shown in Fig. 15, the opening area of the proportional valve is gradually increased. This gradually increases the amount of hydraulic oil that flows through the shock absorber 12. Accordingly, the rear axle 11 is gradually released from the locked state. Thus, sudden swinging of the rear axle 11 is prevented.

In the same manner, the amount of hydraulic oil supplied to the lifting cylinder 6 is controlled by the proportional valve 130. Thus, when the signal outputting signal (f) is cleared, sudden lifting or lowering of the load

on the forks 4 is avoided. Accordingly, the vehicle does not receive a sudden impact from the load on the forks 4. This enables smooth lifting and lowering of loads.

Fig. 16 illustrates a further embodiment according to the present invention. This embodiment employs a first electromagnetic switching valve 41 that is similar to the one used in the first embodiment. Furthermore, a second electromagnetic switching valve 42 substitutes for the throttle valve 17. The second switching valve 42 has a minimal restricting passage 42a and a maximal restricting passage 42b, each of which restrict the flow of hydraulic oil. Hydraulic oil selectively flows through either the minimal restricting passage 42a or the maximal restricting passage 42b. The passage diameter of the minimal restricting passage 42a is greater than the passage diameter of the maximal restricting passage 42b. Thus, the amount of hydraulic oil that passes through the minimal restricting passage 42a is greater than that of the maximal restricting chamber 42b. The controller 31 is connected to the second switching valve 42. The restricting area of the switching valve 42 is adjusted to gradually release the locked state of the rear axle 11.

As shown in Fig. 17, when the locking signal is not output from the controller 31, the minimal restricting passage 42a is selected to allow hydraulic oil flow there-through. In this state, the shock absorber 12 supports the rear axle 11 in an unlocked state. When the controller 31 outputs the locking signal, the maximal restricting passage 42b is selected to allow hydraulic oil flow there-through. When a predetermined time length J elapses after the controller 31 terminates the output of the locking signal, the minimal restricting passage 42a is selected to allow hydraulic oil flow therethrough. This results in the shock absorber 12 releasing the locking of the rear axle 11.

When releasing the rear axle 11 from a locked state, the flow rate of the hydraulic oil supplied to the shock absorber 12 is restricted by the minimal restricting passage 42a. This prevents sudden swinging of the rear axle 11 that may be caused by a sudden increase in the pressure within the shock absorber 12 and ensures stability of the traveling forklift truck 1.

In this embodiment, an electromagnetic proportional valve may substitute for the electromagnetic switching valve 42. Such a structure further prevents sudden swinging of the rear axle 11 when the controller 31 stops the output of the locking signal to have the shock absorber 12 release the rear axle from a locked state.

A further embodiment of the present invention will now be described with reference to Figs. 18 to 20. In this embodiment, a pair of coil springs B connect the rear axle 11 to the body frame 1a to absorb the impact transmitted to the frame 1 from the rear axle 11 when the axle 11 swings as the forklift truck 1 changes directions. In addition, the rear axle 11 is released from a locked state when the centrifugal force  $F_a$  detected by the acceleration sensor 21 becomes smaller a predeter-

mined value. This structure is described in Japanese Unexamined Patent Publication No. 58-211903. However, since the springs B absorb the impact that is transmitted to the entire vehicle as the vehicle is being steered to change directions, the centrifugal force applied to the vehicle may not be accurately detected. As a result, the locking of the rear axle 11 may be released even when the forklift truck 1 is changing directions. This embodiment solves this problem.

As shown in Fig. 18, when the forklift truck 1 changes directions, an actual centrifugal force  $F$  swings the vehicle together with the rear axle 11. During the swinging, the force  $F_s$  of the spring B acts on the rear axle 11. The centrifugal force  $F_a$  detected by the acceleration sensor 21 corresponds to the resultant force of the actual centrifugal force  $F$  and the spring force  $F_s$ .

The controller 31 compares the centrifugal force  $F_a$  with a predetermined maximum reference value  $H_{max}$  and a predetermined minimum reference value  $H_{min}$ . This comparison is carried out in the same manner as illustrated in the flowchart of Figs. 8(A), and 8(B). In this processing, the computed centrifugal force  $F_b$  replaces the centrifugal force  $F_a$ . The controller 31 stops the output of the locking signal when the predetermined time length  $T_a$  elapses after the centrifugal force  $F_a$  decreases from a value equal to or greater than the minimum reference value  $H_{min}$  to a value smaller than the minimum reference value  $H_{min}$ .

Fig. 20 shows how the centrifugal force  $F_a$  detected by the acceleration sensor 21 changes as time elapses when the rear axle 11 is in a locked state during turning of the forklift truck 1. During time period  $X_1$ , the value of the centrifugal force  $F_a$  is smaller than the minimum reference value  $H_{min}$  due to the spring force  $F_s$ . Since the time period  $X_1$  is shorter than the predetermined time length  $T_a$ , the controller 31 continues to output a locking signal to the electromagnetic switching valve. After the vehicle stops turning, the centrifugal force  $F_a$  remains smaller than the minimum reference value  $H_{min}$  during time period  $X_2$ , which is longer than the predetermined time length  $T_a$ . Thus, the controller 31 stops the output of the locking signal when the predetermined time length  $T_a$  elapses. Accordingly, the rear axle 11 remains locked regardless of the centrifugal force  $F_a$  temporarily becoming smaller than the minimum reference value. This ensures stability of the forklift truck 1 when changing directions.

Although several embodiments of the present invention have been described herein, it should be apparent to those skilled in the art that the present invention may be embodied in many other specific forms without departing from the spirit or scope of the invention. Therefore, the present examples and embodiments are to be considered as illustrative and not restrictive and the invention is not to be limited to the details given herein, but may be modified within the scope of the appended claims.

A control apparatus for an industrial vehicle is disclosed. The vehicle has a rear axle that is swingable

upon a straight travel of the vehicle and fixed upon a turning of the vehicle. A damper locks or unlocks the rear axle. A controller has a memory that stores a first value and a second value of an angular velocity rate that represents an angular velocity per a unit time. The controller activates or deactivates the damper. The controller activates the damper to lock the rear axle when the angular velocity rate is greater than the first value. The controller deactivates the damper to unlock the rear axle when the angular velocity rate is kept smaller than the second value for a predetermined time period after the angular velocity rate has become smaller than the second value.

## Claims

1. A control apparatus for an industrial vehicle (1) including a rear axle (11), said rear axle (11) being swingable upon a straight travel of the vehicle (1) and locked based on a parameter with respect to a turning of the vehicle (1), said apparatus characterized by a predetermined first value ( $K_{max}$ ) and a predetermined second value ( $K_{min}$ ) of an angular velocity rate ( $\Delta\omega/\Delta T$ ), wherein said angular velocity rate ( $\Delta\omega/\Delta T$ ) represents an angular velocity ( $\omega$ ) per a unit time, wherein said first value ( $K_{max}$ ) is predetermined to indicate turning of the vehicle (1) when the angular velocity rate ( $\Delta\omega/\Delta T$ ) is greater than the first value ( $K_{max}$ ), and wherein said second value ( $K_{min}$ ) is predetermined to indicate the straight travel of the vehicle (1) when the angular velocity rate ( $\Delta\omega/\Delta T$ ) is smaller than the second value ( $K_{min}$ ) and control means (13, 31) selectively activates and deactivating a damper (12), said control means (13, 31) activates the damper (12) to lock the rear axle (11) when the angular velocity rate ( $\Delta\omega/\Delta T$ ) is greater than the first value ( $K_{max}$ ), said control means (13, 31) deactivates the damper (12) to unlock the rear axle (11) when the angular velocity rate ( $\Delta\omega/\Delta T$ ) is kept smaller than the second value ( $K_{min}$ ) for a predetermined time period ( $T$ ) after the angular velocity rate ( $\Delta\omega/\Delta T$ ) greater than second value ( $K_{min}$ ) has lowered below the second value ( $K_{min}$ ).
2. The control apparatus as set forth in Claim 1, characterized by first detecting means (20) for detecting an angular velocity ( $\omega$ ) of the vehicle (1) and first computing means (31) for computing the angular velocity rate ( $\Delta\omega/\Delta T$ ), said first computing means (31) differentiated the angular velocity ( $\omega$ ) detected by the first detecting means (20) to obtain the angular velocity rate ( $\Delta\omega/\Delta T$ ).
3. The control apparatus as set forth in Claim 1, characterized by second detecting means (22) for detecting a steering angle ( $\theta$ ), third detecting means (23) for detecting a vehicle velocity ( $v$ ) and second computing means (31) for computing an

angular velocity ( $\omega \times 1$ ) based on the detected steering angle ( $\theta$ ) and the detected vehicle velocity ( $v$ ), said second computing means (31) computing the angular velocity rate ( $\Delta\omega/\Delta T$ ) by differentiating the angular velocity ( $\omega$ ).

4. The control apparatus as set forth in any one of Claims 1 to 3, characterized by a memory (31b) storing said first value ( $K_{max}$ ) and the second value ( $K_{min}$ ) of the angular velocity rate ( $\Delta\omega/\Delta T$ ).
5. The control apparatus as set forth in Claim 4, characterized by that said control means includes a valve (13) selectively open and closed to control a supply of pressurized oil to the damper (12) and a controller (31) for actuating the valve (13) based on a comparison of the angular velocity rate ( $\Delta\omega/\Delta T$ ) and the first value ( $K_{max}$ ) and the second value ( $K_{min}$ ).
6. The control apparatus as set forth in claim 5, characterized by that said controller (31) outputs a signal to the valve (13) to activate the damper (12) when the angular velocity rate ( $\Delta\omega/\Delta T$ ) is greater than the first value ( $K_{max}$ ) and stops outputting the signal when the angular velocity rate ( $\Delta\omega/\Delta T$ ) is smaller than the first value ( $K_{max}$ ) and subsequently smaller than the second value ( $K_{min}$ ).
7. The control apparatus as set forth in Claim 1, characterized by that said controller (31) includes a counter for counting for the predetermined time period after the angular velocity rate ( $\Delta\omega/\Delta T$ ) has become smaller than the second value ( $K_{min}$ ) and stops outputting the signal after the counter has finished counting.
8. The control apparatus as set forth in Claim 7, characterized by that said valve includes an electromagnetic valve (13) that is open based on the signal from the controller (31) and a fluid source (16) for supplying the pressurized fluid to the damper (12) through the electromagnetic valve (13) when the valve (13) is open.
9. The control apparatus as set forth in Claim 7, characterized by that said controller (31) outputs a duty signal with enablements gradually increasing and said valve includes an electromagnetic valve (130) increasing opening in accordance with the enablements of the signal from the controller (31).
10. The control apparatus as set forth in Claim 2, characterized by forth detecting means (23) for detecting a vehicle velocity ( $v$ ), third computing means (31) for computing a centrifugal force ( $F_b$ ) acting on the vehicle (1) based on the angular velocity ( $\omega$ ) detected by the first detecting means (20) and the vehicle velocity ( $v$ ) detected by the forth detecting

means (23) and a memory (31a) for storing a maximum reference value ( $H_{max}$ ) and a minimum reference value ( $H_{min}$ ) with respect to the centrifugal force ( $F_b$ ) computed by the third computing means (31), wherein said control means (31) locks the damper (12) when the centrifugal force ( $F_b$ ) is in excess of the maximum reference value ( $K_{max}$ ), and wherein said control means (31) unlocks the damper (12) when the centrifugal force ( $F_b$ ) that is greater than second value becomes smaller than the minimum reference value ( $H_{min}$ ).

11. The control apparatus as set forth in Claim 1, characterized by fifth detecting means (25) for detecting a weight of a load that is in excess of a predetermined value and outputting a signal and sixth detecting means (24) for detecting a position of the load that is higher than a predetermined position and outputting a signal, wherein said control means is arranged to actuate the valve (13) based the signals from the fifth detecting means (25) and the sixth detecting means (24).
12. The control apparatus as set forth in any one of the preceding claims, characterized by that said first detecting means includes a gyroscope (20).
13. The control apparatus as set forth in Claims 8 or 9, characterized by buffer means including an electromagnetic switching valve (42) disposed between the fluid source (16) and the damper (12) and having two openings different from each other in size, said openings being switched from one to another to adjust pressure in the damper (12), wherein said controller (31) actuates the switching valve (42) to select the smaller opening to slow down the unlocking operation of the damper (12).
14. The apparatus as set forth in Claim 1, characterized by an elastic member (S) for supporting the rear axle (11) to absorb an inclining movement thereof when the vehicle (1) turns and detecting means (21) for detecting an acceleration ( $F_a$ ) of the vehicle (1), wherein said rear axle (12) is locked when the acceleration ( $F_a$ ) is greater than the maximum value ( $H_{max}$ ) and unlocked when the acceleration ( $F_a$ ) is kept smaller than the minimum value ( $H_{min}$ ) for a predetermined time ( $T_a$ ) period after the acceleration ( $F_a$ ) has become smaller than the minimum value ( $H_{min}$ ).
